⑨ USL Technical Memorandum No. 2211-70-67

⑪ 12 June 1967

⑫ 34p.

⑭ USL-TM-2211-70-67 INTRODUCTION

This is a second in a series of memoranda dealing with the gathering and reduction of data collected during "EARS" Cruise I from 28 October to 13 December 1966.

Programs for analysis of EARS I cruise data require continuous range information. Range data gathered is based on skipped projector pulse time and detonation times of explosive charges fired at various depths. The acoustic signals used during the several runs fall into three general cases.

Case 1 - CW pulse only -10 milliseconds, 100 milliseconds, and 1000 milliseconds long; either 1900 Hz and 3800 Hz mixed, or 400 Hz.

Case 2 - Explosive charges only, MK54, MK59-1, MK61-0 or 1 lb TNT blocks w/fuses.

Case 3 - Both CW Pulses and explosive charges with no projector skipped pulse times available.

Range data for case 1 signals are the simplest to calculate. Using the skipped projector pulse time as a reference, the projector to hydrophone travel time of the CW signal is measured and multiplied by C_s ; where C_s is the average horizontal velocity of sound.

Case 2 signal ranges require additional information for calculation. Ship's speed taken from ship's log, detonation depth (preset by fuses, either set or pressure actuated) and observed sink times yield slant range from the ship to the explosive charge.

USL Tech Memo
2211-70-67

$$SR = \sqrt{D^2 + (t.v)^2}$$

where SR = slant range
D = depth of detonation
t = observed sink time
v = ships speed

When the shot is heard through the hull mounted hydrophone, it has already travelled SR. Travel time is measured from this time to when it is received by a hydrophone on the receiving ship. The shot range is then:

$$R_s = T.C_s + SR$$

where R_s = shot range
T = travel time
 C_s = sound velocity
SR = slant range

Case 3 signals, where no skipped projector pulse times are available, require both shot and projector range calculations. Shot range is determined by the method explained above. Projector range is:

$$R_p = R_s + (R_{sp})$$

where R_{sp} = range from projector to shot. The sign of R_{sp} is positive when range is closing, negative when range is opening.

R_{sp} is found by taking the time difference of arrival from the hull mounted hydrophone and the projector mounted hydrophone. The signals from these phones are fed into separate channels of a Sanborn recorder. The time difference is read directly from the chart with

when projector receives the signal before the hull does.

$$R_{ap} = SR + \Delta t . c_s$$

where Δt = time difference of arrival
 c_s = sound velocity
